1999 Colorado Corn Variety Performance Trials

ACKNOWLEDGMENTS

The authors express their gratitude to the Colorado farmers who generously contributed the use of their land, equipment, and time to conduct these trials for the good of all Colorado corn producers: Burlington - Don Sircy; SW Greeley - Jim Geist; Delta - Wayne Brew; Julesburg - Gene Bauerle; Ovid - Dean Pirrie; Olathe - David Seymour; Stratton - Tim Pautler; Wiggins - Larry Rothe; Yuma - Byron Weathers. We also acknowledge the participation of the Agricultural Research, Development and Education Center (ARDEC) - Fort Collins; Central Great Plains Field Station - Akron; Western Colorado Research Center - Fruita; Arkansas Valley Research Center - Rocky Ford.

1999 COLORADO CORN PERFORMANCE TRIALS

Introduction

The importance of corn in Colorado has fluctuated greatly during the last 120 years. The earliest records in Colorado dates back to 1879 when Colorado farmers planted 23,000 acres and yields averaged 19.8 bu/acre. The highest acreage planted to corn in the state was 2.58 million acres in 1934. Average yields of grain corn did not exceed 30 bu/acre until 1956 when 68% of the corn acreage was irrigated. In 1997, the average irrigated corn grain yield was over 160 bu/acre. In recent years, Colorado corn producers annually plant approximately one million acres of hybrid corn, for both grain and silage. Hybrid corn seed, valued more than \$30 million, is purchased every year by Colorado corn producers from hybrid seed corn companies. Variable climatic conditions, innovations from biotechnology, acquisitions and mergers of seed companies, and rapid evolution of new hybrid lines means that unbiased performance information is very important to Colorado corn producers when choosing the best hybrid for their farm.

To provide Colorado corn growers with reliable and unbiased performance information, Colorado State University personnel annually evaluate commercial corn hybrids at multiple locations. Participation by the seed companies in the state trials is voluntary. All commercial companies are given the opportunity to enter one or more hybrids at any location. Reference to commercial companies or hybrids is made with the understanding that no discrimination is intended and no endorsement is implied by Colorado State University.

In 1999 corn grain hybrids were tested under irrigation at six Eastern Colorado locations and three Western Slope locations. Corn hybrids were also tested at three dryland locations in Eastern Colorado. Irrigated silage corn hybrids were tested at two Eastern Colorado locations and two Western Slope locations. Eastern Colorado trials were conducted by Colorado State University's Department of Soil and Crop Sciences, Crops Testing program, and Western Slope trials were conducted by Calvin Pearson of the Fruita Research Center, Colorado Agricultural Experiment Station

A randomized complete block field design with three replicates was used at all Eastern Colorado irrigated trials and four replicates were used in all dryland trials. Target plant populations for the trials were 32,000 and 15,000 seeds per acre for irrigated and dryland trials, respectively. Irrigated trials were planted at 15% above target population and dryland trial target populations were attained by hand thinning. The center two rows (200 ft^2), of four row plots, were harvested for grain yield. Western Slope trials were planted at a target population of 33,500 seeds per acre. Plot area harvested was approximately 230 ft^2 at these sites.

All grain yields are reported in bushels per acre adjusted to 15.5% moisture content. Additional variables reported are grain moisture at harvest, test weight, plant height, lodging and/or stalk breakage, plants per acre, and ear drop. Ears dropped per plot were counted at the time of harvest, but fallen ears are not included in the plot yields. A silk date is reported for the Rocky Ford trial. Silage yields are reported in tons per acre adjusted to 70% moisture content. The moisture content of silage at harvest is reported as an indicator of hybrid maturity. The least significant difference (LSD) value ($\alpha=0.30$) and the coefficients of variation (CV) are reported for yield¹.

The 1999 Cropping Season

The 1999 corn cropping season in eastern Colorado can be characterized by the following observed phenomena:

- average growing degree days (GDD)
- few damaging hail storms
- precipitation was normal or above normal during critical period from July 15 to August 15 for dryland corn
- later than normal killing frost, long dry harvest period with insignificant lodging and ear loss

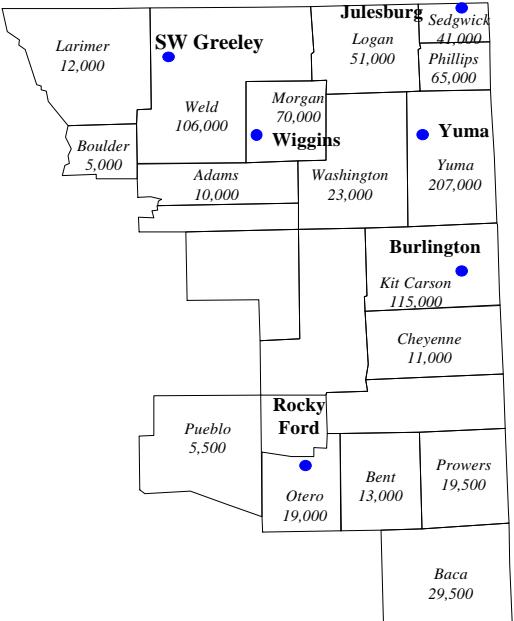

¹Carmer, S.G. 1976. Optimal significance levels for application of the least significant difference in crop performance trials. *Crop Sci.* 16:95-99.

Eastern Colorado Irrigated Grain Corn Performance Data

Each year about 750,000 acres of irrigated corn for grain is planted in Colorado, yielding 120-165 bu/acre, and producing upwards of 100 million bushels of corn with a value over \$150 million. Irrigated corn producers spend over \$20 million a year for seed. CSU conducts hybrid performance trials to provide unbiased and reliable information to Colorado producers so they may select the best hybrids for their farming conditions.

An important climatic factor determining irrigated corn yield is growing degree days. GDD calculations are accumulated from May 1 to September 30 based on daily temperatures as the average daily high and low temperature minus 50° F. For calculating the mean daily temperature, a minimum temperature below 50° F is counted as 50° F, and a maximum above 86° F is counted as 86° F. GDD's in 1999 were close to the long term average GDD at all locations.

Six eastern Colorado irrigated corn trial locations for 1999 and the 1998 corn acreage harvested in seventeen important corn producing counties of Colorado.

Dryland Grain Corn Performance Data

Northeastern Colorado growers have been adopting more intensive dryland cropping systems as shown by increased dryland corn acreage which rose from 26,000 acres in 1990 to 240,000 acres in 1998. Most of the acreage is found in nine NE Colorado counties. Average dryland corn yield in Colorado was 63 bu/acre in 1998.

Table 14. Dryland cultural conditions in 1999

	Akron	Julesburg	Stratton
Soil Type	Rago Silt Loam	Richfield Loam	Keith Silt Loam
Previous Crop	Wheat	Wheat	Wheat
Fertilization			
N lb acre ⁻¹	50	108	80
P ₂ O ₅ lb acre ⁻¹		27	30
K ₂ O acre ⁻¹			0
Zn acre ⁻¹			1
Herbicide	Roundup Frontier Atrazine	Dual II	Marksman
Insecticide	None	None	None

Three northeastern Colorado dryland corn trial locations for 1999 and the 1998 dryland acreage harvested.

Trial Location	1999 GDD	Long Term Average GDD	1999 Precip. 7/15-8/25	% of normal 7/15-8/25
Julesburg	2716	2752	4.33"	148 %
Akron	2614	2571	7.01"	234 %
Stratton	2724	2707	6.16"	197 %

The 1999 dryland trials benefitted from above average precipitation in the critical July-August period at all three locations. Nielsen et al. (1996) determined that 70% of variation in dryland corn yield can be explained by rainfall during the six-week period, from 15 July to 25 August, corresponding to tasseling, silking, and early grain-filling. Grain yields in 1999 were higher at Akron and Stratton where more critical rainfall was received. GDD's in 1999 were close to average long-term GDD at all three trial locations.

Western Slope Grain Corn Performance Data

Over 3,000,000 bushels of corn grain are produced on some 30,000 acres of irrigated farmland on the Western Slope every year, bringing in over \$8 million to local producers. Calvin Pearson of the Colorado Agricultural Experiment Station evaluates long-season and short-season corn grain hybrids to provide reliable and unbiased information to Western Slope producers.

Growing season conditions in 1999 on the Western Slope were favorable for corn production with GDD slightly above average GDD.

Trial Location	1999 GDD	Long Term Average GDD
Fruita	2820	2673
Delta	2623	2590

Two Western Slope corn trial locations for 1999 and the 1998 acreage harvested in four important corn producing counties of the Western Slope.

Corn Silage Performance Data for Eastern Colorado and the Western Slope

Colorado farmers annually cut more than 100,000 acres of corn for silage. Larimer, Weld, Morgan, Logan, Kit Carson, and Montrose counties are the most prominent silage-producing counties in Colorado. Corn seed for silage in Colorado represents annual sales of about \$3 million. Colorado State University personnel evaluate commercial corn silage hybrids at multiple locations to provide reliable and unbiased hybrid performance information to Colorado corn growers.
